## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 22009 was prepared by Technical Committee ISO/TC 20, *Aircraft and space vehicles*, Subcommittee SC 14, *Space systems and operations*.

This second/third/... edition cancels and replaces the first/second/... edition (ISO 4:2005, ISO 22009:2006, ISO 22009:2006, ISO 22009:2006), [clause(s) / subclause(s) / table(s) / figure(s) / annex(es)] of which [has / have] been technically revised.

## Introduction

This standard describes the main requirements to the Earth's magnetospheric magnetic field model. The model satisfying the set of requirements is described in the Annex as working example. The model can be used in scientific and engineering applications and is intended to calculate the magnetic induction field generated from a variety of current systems located on the boundaries and within the boundaries of the Earth's magnetosphere under a wide range of environmental conditions, quiet and disturbed, affected by Solar-Terrestrial interactions simulated by Solar activity such as Solar Flares and related phenomena which induce terrestrial magnetic disturbances such as Magnetic Storms.

# Space Environment (Natural and Artificial). Model of Earth's Magnetic Field.

## 1 Scope

Standard describes the main magnetospheric large-scale current systems and the magnetic field in the Earth's magnetosphere and provides the main requirements to the model of the magnetospheric magnetic field. Ionospheric currents are not considered in this Standard. The standard gives in Annex the working example of the model and establishes the parameters of magnetospheric large-scale current systems which are changing in accordance with conditions in the space environment. Standard can be used to develop the new models of magnetospheric magnetic field. Such models are useful in investigate physical processes in the Earth's magnetosphere as well as in calculations, developing, testing and estimating the results of exploitation of spacecrafts and other equipment operating in the space environment.

The main goals of standardisation of the Earth's magnetospheric magnetic field are:

- providing the unambiguous presentation of the magnetic field in the Earth's magnetosphere;
- providing compatibility of results of interpretation and analysis of space experiments;
- providing less labour-consuming character of calculations of the magnetic field of magnetospheric currents in the space at geocentric distances of 1.0-6.6 Earth's radii ( $R_E$ );
- providing the most reliable calculations of all elements of the geomagnetic field in the space environment.

Magnetic field model presented in the Annex of this standard can be used to forecast radiation situation in the space, including the periods of intense magnetic disturbances (magnetic storms) when developing systems of spacecraft magnetic orientation, when forecasting the influence of magnetic disturbances on transcontinental piping and power transmission lines.

## 2 Terms and Definitions

### 2.1 Internal Magnetic Field

Internal (main) magnetic field is the magnetic field produced by the sources inside the Earth's core. It can be presented in the form of a series of spherical harmonic functions. The expansion coefficients (IGRF model) undergo very slight changes in time. The International Association of Geomagnetism and Aeronomy (IAGA) is responsible for IGRF model development and modifications and approves its coefficients every 5 years. Internal magnetic field is not the subject of this Standard.

### 2.2 External Magnetic Field

External (magnetospheric) magnetic field is the magnetic field produced by magnetospheric sources of magnetic field.

## 2.3 Magnetospheric Sources of Magnetic Field

Magnetospheric sources of magnetic field are

- Currents flowing over the magnetopause and screening the geomagnetic dipole magnetic field.
- Currents flowing inside the Earth's magnetosphere:
  - tail current, produced by currents across the geomagnetic tail and closure currents on the magnetopause;
  - ring current, including symmetrical ring current, circling around the Earth and carried by trapped particles and partial ring current, produced by currents flowing outside the region of symmetrical ring current, mostly in the pre-midnight sector of equatorial plane, closed by field-aligned and ionospheric currents;
  - Field-aligned currents, produced by currents flowing along the auroral magnetic field lines, closed by currents on the magnetopause and in the ionosphere.
- Currents flowing over the magnetopause and screening the ring current and partial ring current magnetic fields.

Electric currents flowing entirely in the ionosphere (ionospheric currents) contribute to the magnetic field variation at altitudes below 1000km. In the region above 1.5 Re effect of ionospheric current is insignificant. Magnetic field of ionospheric currents is not the subject of this Standard.

## 2.4 Geomagnetic Dipole Tilt Angle

Geomagnetic dipole tilt angle is the angle of inclination of the geomagnetic dipole to the plane orthogonal to the Earth-Sun line.

## 2.5 Solar-Magnetospheric Coordinates

Solar-magnetospheric (GSM) coordinates are the Cartesian geocentric coordinates, where X-axis is directed to the Sun, Z-axis lies in the one plane with OX axis and geomagnetic dipole axis and Y-axis supplements the X and Z axes to the right-hand system.

## 2.6 Magnetopause Stand-off Distance

Magnetopause stand-off distance is the geocentric distance to the subsolar point on the magnetopause.

# 3 General Concepts and Assumptions

## 3.1 Magnetic Field Induction in the Earth's Magnetosphere

Vector of magnetic field induction  $\vec{B}_M$  in the Earth's magnetosphere is calculated by the formula

$$\vec{B}_M = \vec{B}_1 + \vec{B}_2, \quad \text{nT}, \quad (1)$$

where  $\vec{B}_1$  is the vector of induction of the internal magnetic field,  $\vec{B}_2$  is the vector of induction of the external magnetospheric magnetic field. The magnetic field of the magnetospheric currents (external magnetic field),  $\vec{B}_2$ , is calculated in terms of the quantitative model of the magnetosphere.

### 3.2 Magnetospheric Magnetic Field Standardisation: Process Based Approach

The magnetospheric magnetic field standard does not specify a single magnetospheric model, theoretical or empirical. In order to encourage continual improvements in magnetospheric modelling, this standard is process-based standard for determining the magnetospheric magnetic field. Magnetospheric magnetic field model, after its development, may satisfy the requirements in Section 4 and the list of criteria presented in Section 5. The working example of the model is presented in the Annex A and must be reconsidered every 5 years on the base of competitions of the candidate models. The current working example is presented in the Annex A.

## 4 Model Requirements

- The model of the magnetic field of magnetospheric currents (referred to below as "model") presents the vector of induction of magnetospheric currents in solar-magnetospheric coordinates.
- The model describes a regular part of the magnetic field in the region from  $1.0 R_E$  to  $6.6 R_E$ .
- The model reflects compression of the Earth's magnetosphere in the dayside due to interaction with the solar wind, day-night asymmetry (the field on the nightside is weakened), day and season variations.
- The model takes into account geomagnetic dipole tilt angle, varying in the range from  $-35^\circ$  to  $+35^\circ$ .

### 4.1 The magnetospheric Magnetic Field Sources

The standardised magnetospheric magnetic field is produced by currents described in Section 2.3. Ionospheric currents' effect is not considered in this Standard.

### 4.2 Parameterization

Each magnetospheric source of magnetic field depends on parameters which are calculated from empirical data.

### 4.3 Magnetospheric Dynamics

The magnetospheric dynamics is determined to be a sequence of its instant states.

### 4.4 Model Testing and Comparison with Measurements

The model testing is carrying out with the help of databases which include the spacecraft based and on-ground measurements. The dataset used for the model testing is presented in the Annex C.

## 5 List of Criteria

The compliance criteria for this standard consist from the activities common for any candidate magnetospheric magnetic field model. These criteria specify the compliance process which includes the model documenting, publishing and testing.

- The candidate model is required to include the statement of the modeling approach used (empirical or theoretical model). The empirical models are required to include a clear specification of the input data used to derive the model and where these data were measured. Theoretical models are required to include a description of the physical principles and approaches that are used as the basis of the model.
- The statement about the candidate model area of application and domain applicability should be included.

- The statement about the rms errors during the model calculations comparison with observational data obtained from measurements should be included. For empirical models, the comparisons should also be made with data, different from those from which the model was built.
- The description and implementation of the magnetospheric magnetic field model should be published in internationally-accessible refereed journals.

## Annex A (informative)

### Paraboloid Model of the Magnetospheric Magnetic Field: Calculation of Induction of the Magnetic Field of the Magnetospheric Currents

The magnetospheric magnetic field calculated by paraboloid model is the solution of the magnetostatic problem inside the paraboloid of revolution.

#### A.1 Paraboloid Model of the Magnetic Field of Magnetospheric Currents

Vector of induction of the magnetic field of magnetospheric currents is calculated by formula

$$\vec{B}_2 = \vec{B}_{sd}(\psi, R_1) + \vec{B}_t(\psi, R_1, R_2, \Phi_\infty) + \vec{B}_r(\psi, b_t) + \vec{B}_{sr}(\psi, R_1, b_r) + \vec{B}_{fac}(I_0). \quad (2)$$

Here

- $\vec{B}_{sd}$  is the magnetic field of currents on the magnetopause screening the dipole field;
- $\vec{B}_t$  is the magnetic field of the magnetospheric tail;
- $\vec{B}_r$  is the magnetic field of the ring current;
- $\vec{B}_{sr}$  is the magnetic field of currents on the magnetopause, screening the ring current field;
- $\vec{B}_{fac}$  is the magnetic field of Region 1 field-aligned currents.

The components of the magnetic field of magnetospheric currents,  $\vec{B}_{sd}$ ,  $\vec{B}_t$ ,  $\vec{B}_r$ ,  $\vec{B}_{sr}$ ,  $\vec{B}_{fac}$  are calculated separately in terms of the paraboloid model of the magnetosphere in the form of series in the Bessel functions or Legendre polynomials.

##### A.1.1 Parameters

The components of the magnetic field of magnetospheric currents,  $\vec{B}_{sd}$ ,  $\vec{B}_t$ ,  $\vec{B}_r$ ,  $\vec{B}_{sr}$ ,  $\vec{B}_{fac}$  are determined by the values of parameters of the magnetospheric current systems:

- $\psi$  is the geomagnetic dipole tilt angle, degrees;
- $\vec{R}_1$  is the distance to the subsolar point at the magnetopause,  $R_E$ ;
- $\vec{R}_2$  is the distance to the earthward edge of the magnetospheric tail current sheet,  $R_E$ ;
- $\Phi_\infty$  is the magnetic flux in the tail lobes, defining the current intensity in the magnetotail, Wb;

- $b_r$  is the intensity of the ring current magnetic field at the Earth's centre, nT;
- $I_0$  being for total Region 1 field-aligned currents intensity, MA.

### A.1.2 Submodels

The instant values of the parameters of the magnetospheric current systems,  $\psi$ ,  $\bar{R}_1$ ,  $\bar{R}_2$ ,  $\Phi_\infty$ ,  $b_r$ ,  $I_0$  are determined using a limited set of empirical data in terms of the so-called submodels (see Annex B).

## A.2 Magnetic Field of the Magnetopause Currents Screening the Geomagnetic Dipole

The,  $\vec{B}_{sd}$ , is calculated as

$$\vec{B}_{sd} = -\nabla U_{sd},$$

where the scalar potential  $U_{sd}$  of the magnetic field of magnetopause currents is presented in spherical coordinates  $R, \theta, \varphi$  (see Annex C.1):

$$U_{sd} = -\frac{M_E}{R_1^2} \sum_{n=1}^{\infty} \left(\frac{R}{R_1}\right)^n [d_n^{\parallel} \sin \psi \cdot P_n(\cos \theta) + d_n^{\perp} \cos \psi \cos \varphi \cdot P_n^1(\cos \theta)], \quad (3)$$

$$P_n = (2^n n!)^{-1} \cdot (d^n (x^2 - 1)^n / dx^n), \quad P_n^1(x) = \sqrt{1 - x^2} \cdot (dP_n / dx).$$

$M_E = B_0 \cdot R_E^3$  is the magnetic moment of the geomagnetic dipole,  $B_0$  is the magnetic field at the geomagnetic equator of the Earth. The first six dimensionless coefficients  $d_n^{\parallel}$  and  $d_n^{\perp}$  are listed in Table 1.

**Table A.1 — Expansion coefficients for the scalar potential of the magnetic field of magnetopause currents**

n	$d_n^{\perp}$	$d_n^{\parallel}$
1	0.6497	0.9403
2	0.2165	0.4650
3	0.0434	0.1293
4	-0.0008	-0.0148
5	-0.0049	-0.0160
6	-0.0022	-0.0225

### A.3 Magnetic Field of the Tail Current System

The magnetic field of the tail current system  $\vec{B}_t$  is calculated from the equation

$$\vec{B}_t = -\nabla U_t + \vec{B}_{t_{in}} \quad (4)$$

Where  $U_t$  is determined by the series

$$U_t = b_t R_1 \begin{cases} \sum_{k,n=1}^{\infty} (b_{nk} + c_{nk} K_n'(\lambda_{nk} \alpha_0) \lambda_{nk}) \cos n\varphi \cdot J_n(\lambda_{nk} \beta) I_n(\lambda_{nk} \alpha) & \text{for } \alpha < \alpha_0 \\ \beta_t \alpha_0 \ln \alpha \cdot \text{sign}\left(\frac{\pi}{2} - |\varphi|\right) + \\ \sum c_{nk} \cos n\varphi \cdot I_n'(\lambda_{nk} \alpha_0) \lambda_{nk} J_n(\lambda_{nk} \beta) K_n(\lambda_{nk} \alpha) & \text{for } \alpha \geq \alpha_0 \end{cases}$$

$$\text{here } c_{nk} = b_{nk} \lambda_{nk} I_n(\lambda_{nk} \alpha_0), \quad b_{nk} = \frac{2\lambda_{nk} \int_0^1 \int_{-\pi}^{\pi} J_n(\lambda_{nk} \beta) f(\beta, \varphi) \cos n\varphi d\varphi d\beta}{\pi(\lambda_{nk}^2 - n^2) J_n^2(\lambda_{nk}) I_n'(\lambda_{nk} \alpha_0)}$$

$$f(\beta, \varphi) = \begin{cases} \frac{\alpha_0}{\beta_t} \beta \cos \varphi, & \text{for } \alpha_0 \beta \cos \varphi < \beta_t \\ \text{sign}\left(\frac{\pi}{2} - |\varphi|\right), & \text{for } \alpha_0 \beta \cos \varphi \geq \beta_t \end{cases},$$

where  $\lambda_{nk}$  are zeros of the  $J' = 0$  equation,  $\alpha_0 = \sqrt{1 - 2R_2/R_1}$  is the parabolic  $\alpha$ -coordinate of the inner edge of the tail current sheet,  $\beta_t = \frac{d}{R_1}$ ,  $d$  is the half thickness of the current sheet,  $b_t = \frac{2\Phi_{\infty}}{\pi R_1^2} \sqrt{R_1/(2R_2 + R_1)}$ , is a magnetic field in the tail lobe at the inner edge of the tail current sheet.

The magnetic field inside the current sheet,  $B_{t_{in}}$ , is calculated from the relations

$$B_{t_{in}\alpha} = b_t \frac{\alpha_0}{\alpha} \frac{\beta}{\beta_t} \frac{\cos \varphi}{\sqrt{\alpha^2 + \beta^2}}, \quad B_{t_{in}\beta} = 0, \quad B_{t_{in}\varphi} = 0.$$

Description of the paraboloid coordinates is presented in the Annex C.3.

### A.4 Ring Current Magnetic Field

The ring current magnetic field  $\vec{B}_r$  is determined by the expressions

$$\vec{B}_r = \frac{M_R}{M_E} \cdot \begin{cases} \left(\frac{R}{R_{rc}}\right)^5 \cdot \vec{B}_d + 2B_0 \frac{R_E^3}{R_2^3} \left(\frac{R_2^5}{R_{rc}^5} - 1\right) \vec{e}_z & \text{for } 0 \leq R \leq R_2 \\ \vec{B}_d & \text{for } R \geq R_2 \end{cases} \quad (5)$$

where  $R_{rc} = \sqrt{0.5(R^2 + R_2^2)}$ ,  $M_R = 0.5b_r \cdot R_2^3 / (4\sqrt{2} - 1)$  is the magnetic moment of the ring current,  $\vec{B}_d$  is the magnetic field of the geomagnetic dipole,  $\vec{e}_z$  being a unite vector directed oppositely to the geomagnetic dipole.

Expressions for  $\vec{B}_d$  and  $\vec{e}_z$  in the solar-magnetospheric coordinates are presented in Annex C.4.

### A.5 Magnetic Field of the Magnetopause Currents Screening the Ring Current

The magnetic field of the magnetopause currents screening the ring current  $\vec{B}_{sr}$  is calculated from the equation

$$\vec{B}_{sr} = -\nabla U_{sr},$$

where the scalar potential  $U_{sr}$  of the magnetic field of magnetospheric currents presented in spherical coordinates  $R, \theta, \varphi$  (see Annex C.2) reads

$$U_{sr} = -\frac{M_R}{M_1^2} \sum_{n=1}^{\infty} \left(\frac{R}{R_1}\right)^n [d_n^{\parallel} \sin \psi \cdot P_n(\cos \theta) + d_n^{\perp} \cos \psi \cos \varphi \cdot P_n^1(\cos \theta)]. \quad (6)$$

Coefficients  $d_n^{\parallel}$  and  $d_n^{\perp}$  are listed in Table 1.

### A.6 Magnetic Field of Field-Aligned Currents

The magnetic field of field-aligned currents  $\vec{B}_{fac}$  is calculated from the equation

$$\vec{B}_{fac} = \text{curl} \vec{A}_{fac}$$

where the vector potential  $\vec{A}_{fac}$  of the magnetic field of field-aligned currents is presented in spherical coordinates  $R, \theta, \varphi$  with polar axis directed opposite the Earth's dipole (see Annexes C2, C.4):

$$\vec{A}_{fac} = \frac{\mu_0 I_0 \sin \varphi}{2(1 + \cos \theta_m)} \begin{cases} \frac{\tan(\theta/2)}{\tan(\theta_m/2)} & \text{for } 0 \leq \theta \leq \theta_m \\ \frac{\sin \theta_m}{\sin \theta} & \text{for } \theta_m \leq \theta \leq \pi - \theta_m \\ \frac{\cot(\theta/2)}{\tan(\theta_m/2)} & \text{for } \pi - \theta_m \leq \theta \leq \pi . \end{cases}$$

$\theta_m$  - is polar cap radius in radians:  $\sin^2 \theta_m = 3.9 \cdot \Phi_\infty [\text{MWb}] / |B_0 [\text{nT}]|$ .

## A.7 Accuracy of the Model

- 1) Comparison with the Large Magnetosphere Magnetic Field Data Base [Faierfield et al., 1994].

Analysis of distribution of relative discrepancies integral over the whole experimental material have the discrepancy mean value about +3%,  $\sigma$  of the distribution is about 80%.

- 2) Comparisons with Dst and satellite measurements

RMS errors are about 10% -15% of peak Dst for different magnetic storms.

The comparison of the model calculations with the empirical data is presented in detail in the Explanatory Report and published in [Alexeev et al., 2001; Alexeev et al., 2003; Kalegaev et al., 2005; Feldstein et al., 2005].

## A.8 The other Relevant Models

- 1) Semi-empirical T96 model by [Tsyganenko, 1995];
- 2) Semi-empirical T01 model by [Tsyganenko, 2001a; 2001b];
- 3) Semi-empirical T04 model by [Tsyganenko, 2005].

The models parameterization is performed using large magnetospheric databases, different for different models. Several model revisions reflect the different mathematical description of the major sources of the magnetospheric field and their different parameterization. The most popular T01 model parameters are geomagnetic dipole tilt angle, IMF By and Bz components, solar wind dynamic pressure, and Dst - index. An attempt is made to take into account the prehistory of the solar wind by introducing two functions, G1 and G2, that depend on the IMF Bz and solar wind velocity and their time history.

## Annex B (informative)

### Submodels

#### B.1 Submodels: Calculation of the Main Parameters of Magnetospheric Current Systems

In the paraboloid model of the magnetosphere the values of parameters of the magnetospheric current systems are calculated using submodels. The submodels represent empirical relations or auxiliary models to relate parameters of the magnetospheric current systems to the measured data. While the magnetic field dependence on parameters is fixed, the parameters dependence on empirical data can be changed by model's user. Below are the simple submodels allowing calculating the model input parameters. These submodels are not the standardisation objects.

##### B.1.1 The Tilt Angle of Geomagnetic Dipole

The tilt angle of geomagnetic dipole,  $\psi$ , is calculated by the formula

$$\sin \psi = -\sin \beta \cos \alpha_1 + \cos \beta \sin \alpha_1 \cos \varphi_m, \quad (7)$$

where

- $\alpha_1 = 11.43^0$  is the angle between the Earth's axis and the geomagnetic dipole moment,
- $\beta$  is the Sun's deflection ( $\sin \beta = \sin \alpha_2 \cos \varphi_{se}$ ),
- $\alpha_2 = 23.5^0$  is the angle between the Earth's axis and the normal to the ecliptic plane,
- $\varphi_{se} = 0.9856263(172 - I_{day})$  is angle between Earth-Sun line and the projection of the Earth's axis at the ecliptic plane,
- $I_{day}$  is the number of the day in a year,
- $\varphi_m = UT \cdot 15^0 - 69.76^0$  is the angle between the midnight geographic meridian plane and northern magnetic pole meridian plane,
- $UT$  is the universal time in hours.

##### B.1.2 The Distance from the Earth to the Subsolar Point on the Magnetopause

The geocentric distance  $R_1$  to the subsolar point is calculated using solar wind data: solar wind dynamical pressure and IMF Bz component [Shue et al., 1998]:

$$R_1 = \{10.22 + 1.29 \tanh[0.184(B_z + 8.14)]\} (nv^2)^{-\frac{1}{6.6}}.$$

Here  $B_z$  is IMF z-component in nT,  $n, v$  are solar wind concentration and velocity in  $\text{cm}^{-3}$  and km/s, respectively.

### B.1.3 The Distance to the Earthward Edge of the Geomagnetic Tail Current Sheet

The distance to the earthward edge of the geomagnetic tail current sheet,  $R_2$ , is calculated by the formula

$$R_2 = 1 / \cos^2 \varphi_k, \quad (9)$$

where  $R_2$  is expressed in  $R_E$ , and  $\varphi_k$  is the latitude of the equatorward boundary of the auroral oval at midnight.

### B.1.4 Magnetic Flux Through the Magnetotail Lobes

Magnetic flux through the magnetotail lobes,  $\Phi_\infty$ , is calculated by the formula

$$\Phi_\infty = \Phi_0 + \Phi_s \quad (10)$$

where  $\Phi_0$  is the magnetic flux in the magnetotail during quiet periods,  $\Phi_s$  being the time-dependent magnetic flux in the lobes associated with intensification of the magnetotail current system during disturbances

$$\begin{aligned} \Phi_0 &= 3.7 \cdot 10^8 \text{ Wb} \\ \Phi_s &= -AL \frac{\pi R_1^2}{14} \sqrt{\frac{2R_2}{R_1} + 1}, \end{aligned} \quad (11)$$

where  $AL$  is the auroral index of geomagnetic activity.

### B.1.5 The Ring Current Magnetic Field at The Earth's Centre

The ring current intensity is characterised by the value of ring current magnetic field at the Earth's centre, which is calculated by the Dessler-Parker-Scopie relation

$$b_r = -\frac{2}{3} B_0 \frac{\varepsilon_r}{\varepsilon_d}, \quad (12)$$

where  $\varepsilon_r$  is the total energy of ring current particles,  $\varepsilon_d = \frac{1}{3} B_0 M_E$  is the geomagnetic dipole energy.

### B.1.6 The Total Region 1 Field-Aligned Current

The total Region 1 field-aligned current intensity is calculated by the formula

$$I_0 = 2 \sqrt{\frac{v}{400}} \cdot \left(\frac{5}{n}\right)^{1/8} \cdot \begin{cases} 0.327744 & \text{for } b_z > -1.6nT \\ -1.017 \cdot \frac{b_z}{5} & \text{for } b_z \leq -1.6nT \end{cases} \quad (13)$$

where  $b_z$  is IMF north-south component, nT, solar wind velocity  $v$  and proton concentration  $n$  are the same as in B.1.2.

## Annex C (informative)

### C.1 Spherical Coordinates (1)

**Spherical coordinates**  $R, \theta, \varphi$  with the polar axis plotted along the Sun-Earth axis are determined by the expressions

$$\begin{aligned}x / R_1 &= R \cos \theta \\y / R_1 &= R \sin \theta \sin \varphi \\z / R_1 &= R \sin \theta \cos \varphi\end{aligned}\tag{14}$$

where  $x, y, z$  are the solar-magnetospheric (GSM) coordinates,  $\theta$  is the polar angle plotted from  $x$  axis,  $\varphi$  being the azimuths angle plotted counterclockwise from  $z$  axis.

### C.2 Spherical Coordinates (2)

**Spherical coordinates**  $R, \theta, \varphi$  with the polar axis plotted opposite the Earth dipole moment are determined by the expressions

$$\begin{aligned}x / R_1 &= R \sin \theta \cos \varphi \\y / R_1 &= R \sin \theta \sin \varphi \\z / R_1 &= R \cos \theta\end{aligned}\tag{15}$$

where  $x, y, z$  are the solar-magnetic (SM) coordinates,  $\theta$  is the polar angle plotted from  $z$  axis,  $\varphi$  being the azimuths angle plotted counterclockwise from  $x$  axis.

### C.3 Parabolic Coordinates

**Parabolic coordinates**  $\alpha, \beta, \varphi$  with the polar axis plotted along the Sun-Earth axis are determined by the expressions

$$\begin{aligned}2x / R_1 &= \beta^2 - \alpha^2 + 1 \\y / R_1 &= \alpha\beta \sin \varphi \\x / R_1 &= \alpha\beta \cos \varphi\end{aligned}\tag{16}$$

where  $x, y, z$  are the GSM coordinates,  $\varphi$  being the azimuths angle plotted counterclockwise from  $z$  axis. In the magnetospheric paraboloid model the magnetopause is the  $\beta = 1$  surface.

#### C.4 Magnetic Field of Geomagnetic Dipole

$\vec{B}_d$  and  $e_{z_{sm}}$  in the solar-magnetospheric coordinates are described by the expressions

$$\begin{aligned}\vec{B}_d &= -\nabla V_d \\ V_d &= \left(\frac{R_e}{R}\right)^3 B_0 \cdot (z \cos \psi - x \sin \psi) \\ \vec{e}_z &= (-\sin \psi; 0; \cos \psi).\end{aligned}\tag{17}$$

#### C.5 Dataset for Model Testing

The Large Magnetospheric Data Base [Fierfield et al., 1994] is used for the testing of the candidate models.
